Abstract:
Introduction: Many manual procedures have long been involved in the management of chronic obstructive pulmonary disease (COPD). Few literatures evaluated the COPD responses to individual or multiple manipulative techniques, so effects are unclear and poorly understood.

Objective: To determine the effectiveness of diaphragmatic manipulation along with conventional physiotherapy on respiratory parameters for patients with chronic obstructive pulmonary disease. Methodology: 30 participants (age range: 40 to 70 years) from National Institute of Diseases of Chest and Hospital (NIDCH) from Mohakhali, Dhaka with chronic obstructive pulmonary diseases (COPD) were included in the study. Diaphragmatic manipulation was applied to experimental group. The conventional treatment was given for 6 sessions/two week including 3 repetitions in one session in 3 session a day of no less than 30 minutes duration for consecutive 2 weeks. Experimental research design measured by using mean, standard deviation, paired t test, independent –t test was taken.
Result: Significant difference between Pre and Post values of all components of respiratory assessment questionnaires showing the effectiveness of diaphragmatic manipulation in reducing pulse rate and improving pulse rate and oxygen saturation rate in 6-minute walk test. Moreover within group comparison in experimental and control group it was found that all the respiratory parameters were significant through diaphragmatic manipulation along with conventional physiotherapy and conventional physiotherapy but only oxygen saturation rate in control group it was not significant. Conclusion: Diaphragmatic manipulation along with conventional physiotherapy yields statistically as well as clinically significant improvements in both pulse rate and six minute walk test in patient with COPD between the ages of 40 and 70 years.

Keywords: Diaphragmatic manipulation, Chronic Obstructive Pulmonary Disease.

1. Introduction: Chronic obstructive pulmonary disease (COPD) is a lung disease characterized by chronic obstruction of lung airflow that interferes with normal breathing and is not fully reversible1. The Global Initiative for Chronic Obstructive Lung Disease (GOLD) defined Chronic Obstructive Pulmonary Disease (COPD) as airflow limitation that tends to not be fully reversible and which is usually both progressive and associated with an abnormal inflammatory response of the lungs to noxious particles or gases6.

COPD burden is born by 11 Asian countries and Asian Pacific Society of Respiratory Diseases 6.2% of the global. In Nepal, COPD accounts for 43% of the non-communicable disease burden, and 2.56% of hospitalizations. Tobacco smoking is the primary cause of COPD, indoor air pollution from biomass and/or traditional fuels is predictable to be associated with 0.4 million deaths from acute symptoms of COPD4.

In Bangladesh the prevalence of COPD is 13.5% and more occurring aged 40 years or older. Illiteracy, smoking and biomass fuel burning are modifiable determinants of COPD. And also found higher among rural than urban residents and in males than females2. Tobacco smoking is thought to be the main risk factor for developing COPD but other environmental exposures including biomass fuel exposure and air pollution may also contribute in developing COPD5. Diaphragmatic manipulation is an effective PNF technique helps in improving breathing pattern and respiratory muscle activity; The inter costal stretch enhances the chest wall elevation and increase chest expansion and diaphragm excursion to improve intrathoracic lung volume which contributes to improvement in flow rate percentage.

2. Materials & Methods:

2.1 Study design: The study was conducted by using an Experimental Research design with two different groups. Only the experimental group received diaphragmatic manipulation along with conventional physiotherapy while in control group received only conventional physiotherapy treatment. This was the study of single blinded Experimental Research design and data collectors were blinding in this study.

2.2 Study place: The study was conducted during February 2017 to May 2017 at National Institute of diseases of chest & hospital (NIDCH), Mohakhali because there have a lot of COPD patients admitted there.

2.3 Ethics approval: The research proposal was submitted to the Institute Review Board (IRB) of BHPI for oral presentation. Then the IRB was approved the proposal. The permission from the concerned authorities obtained ensuring the safety of the participants. In order to eliminate ethical claims, the participants set free to receive treatment for other purposes as usual. Each participant informed about the study before beginning and given written research proposal was submitted to the Institutional Review consent.

2.4 Inclusion criteria: Age ranged from 40-70 years, with moderate stage of COPD3. No clinical evidence of obvious exercise limiting cardiovascular or neuromuscular diseases. All participants were not involved in previous rehabilitation program at least 4 months prior to the study and had no recent infectious
exacerbations for the 2 months preceding the study, with no history of psychiatry or psychological disorders. Initial medical screening was performed for each patient prior to the study\(^3\).

2.5 Exclusion criteria: Patients were excluded if they had significant or unstable cardiac, musculoskeletal or psychological problems or medication that could affect or interfere with their performance or affect their safe participation, any known abdominal pathologies, history of gastroesophageal reflux, any degree, persistent hiccups within previous three months, a history of serious injury to the spine or thorax, including costal or spinal fractures or history of diaphragm surgery, bronchial asthma or restrictive lung disease or receiving long-term oxygen therapy\(^3\).

2.6 Sample size: Thirty patients with COPD was selected randomly than 15 patients was randomly assigned to Diaphragmatic manipulation with conventional physiotherapy group and 15 patients to the only conventional physiotherapy group for this experimental research design. The samples were given numerical number C1, C2, C3 etc. for the control group and E1, E2, E3 etc. for experimental group.

2.7 Subjects: All participants were asked to continue their drug therapies, regular diet and normal daily activities throughout the study. Patients in experimental group received diaphragmatic manipulation along with conventional therapy and patients in control group received only conventional therapy.

2.8 Outcome measures:

Written questionnaire, spirometry, pulse oximeter

3. Results:

Patient in the study were aged between 41 to 70 years old (the mean age in experimental group was 60 years whereas in control group 62 years). There were of 60% (n=18) male and 40% (n=12) female.

**Table-3: Within group comparison of respiratory parameters**

In this way experimental group pulse rate (p=.00), oxygen saturation rate (p=.00), pulse rate in 6 minute walk test (p=.002), oxygen saturation rate in 6 min walk test (p=.00), it shows significant. It indicates that diaphragmatic manipulation along with conventional physiotherapy was effective for those variables. In comparison control group pulse rate (p=.00), oxygen saturation rate (p=.08), pulse rate in 6 minute walk test (p=.002), oxygen saturation rate in 6 min walk test (p=.00) was significant. It indicates that conventional physiotherapy was effective for those variables but only for oxygen saturation rate this treatment was not significant.

**4. Discussion:**

Study demonstrated that among thirty participants in both experimental and control group pulse rate, oxygen saturation rate and oxygen saturation rate after 6 minute walk test it was significant. It indicates that diaphragmatic manipulation along with conventional physiotherapy whether as only conventional physiotherapy had a great impact on reducing pulse rate and improving functional capacity in patients with moderate type of COPD.

**5. Conclusion:**

Functional outcomes of COPD patients may be limited by pulmonary, musculoskeletal constraints and low functional capacity. Diaphragmatic manipulation procedures yielded significant benefits on both pulmonary function and functional capacity in patients with moderate COPD. Furthermore; results reported better responses of pulmonary function and functional capacity to combined application of both procedures. Furthermore, COPD is the world burden for disability.
